# INFORMATION RECORDING MEDIUM

## BACKGROUND OF THE INVENTION

### 5    Field of the Invention:

        The present invention relates to an information recording medium utilized for an optical recording/reproducing apparatus, which reads out information recorded on the information recording medium by making the information recording medium  
10    relatively move, particularly, relates to an information recording medium comprising a read only area of enabling to read out information and a recording/reproducing area of enabling to record and reproduce information.

### 15    Description of the Related Art:

        Currently various types of information recording mediums such as in a disk shape, in a card shape, and in a tape shape are utilized as an optical information recording medium from which information is read out by making the information recording  
20    medium relatively move. Such information recording mediums are divided into two types in consideration of mechanism of recording or reproducing: one is a read only type and the other is a recording/reproducing type, that is, a recordable type and an overwritable type. A read only type information recording medium  
25    is shipped out into a market with being prerecorded with information such as a CD audio disk typically, and is reproduced by a user. On the other hand, a recordable or overwritable type information recording medium is shipped out into a market

without any recorded information, and a user records information on it and reproduces it if necessary.

A problem arises along with a trend toward multimedia causing to increase a chance such that copyright is infringed by using an electronic means. Accordingly, in order to prevent such the problem, an idea such as embedding a specific code, which can not be rewritten by a user, is necessary to be realized even in a recordable or overwritable type information recording medium, which can be recorded freely by a user.

As mentioned above, various kinds of information recording mediums, which are provided with two areas composed of a read only area and a recording/reproducing area, have been introduced. For example, there is existed an information recording medium provided with a recording/reproducing area only in a predetermined angle. Further, another information recording medium having a recording/reproducing area, which is provided with a read only area allocated in each one half track, is introduced.

Furthermore, an information recording medium provided with both a read only area and a recording/reproducing area, which are allocated in different positions from each other, is introduced. Fig. 2 is a cross sectional view of such the information recording medium 301. In Fig. 2, the information recording medium 301 comprises a substrate 10, a recording layer 13, and a resin layer 14. A microscopic pattern is formed on a surface of the substrate 10 at a boundary area between the substrate 10 and the recording layer 13. Microscopic patterns constituting a read only area and a recording/reproducing area are engraved in areas

corresponding to the read only and recording/reproducing areas respectively. Actually, microscopic patterns 11 corresponding to the read only area and other microscopic patterns 12 corresponding to the recording/reproducing area are engraved.

5 These microscopic patterns 11 and 12 are different from each other in depth. A depth "d1" of the microscopic patterns 11 is  $\lambda/4n$ , on the other hand, a depth "d2" of the microscopic patterns 12 is  $\lambda/8n$ , wherein  $\lambda$  is a reproduction wavelength of a laser beam and "n" is a refractive index of the substrate 10 at the reproduction wavelength  $\lambda$ . Specifying the depth of the microscopic patterns 11 to  $\lambda/4n$  is caused by a phase depth in which a signal output from the read only area becomes maximum. Further, specifying the depth of the microscopic patterns 12 to  $\lambda/8n$  is caused by that a push-pull signal related to tracking of the information recording medium becomes a maximum output.

10

15

As mentioned above, allocating two areas in different positions reduces load of a recording/reproducing apparatus due to a simplified layout. Accordingly, there is much merit.

However, there is existed a following problem of the prior art mentioned above. A defect has occurred when an information recording medium formed with microscopic patterns shown in Fig. 2 has been loaded in various recording/reproducing apparatuses, which are currently available in a market, and operated. A mode of the defect is out of tracking while reproducing the information recording medium with continuously traversing from a recording/reproducing area to a read only area. Further, an operation traversing reversely from the read only area to the recording/reproducing area is also defective. According to our

20

25

careful investigation of the problem, it is found that a recording/reproducing apparatus employs a push-pull method for tracking so as to record information in a groove and the push-pull method does not match with the information recording medium

5 301. In other words, firstly, the problem is caused by that forming the read only area in the depth of  $d1 = \lambda / 4n$  results a push-pull signal output in zero. In a case that the push-pull signal output is zero, a track can not be detected. Therefore, the reproduction stops at the track. Further, as a second problem, output difference

10 between a push-pull signal output of the read only area and a push-pull signal output of the recording/reproducing area is large, so that a servo system of the recording/reproducing apparatus can not follow properly. Accordingly, it is required to solve such the problem as out of tracking when an information recording medium

15 having two areas is actually recorded and reproduced.

## SUMMARY OF THE INVENTION

20 Accordingly, in consideration of the above-mentioned problems of the prior art, an object of the present invention is to provide an information recording medium, which can solve the problem mentioned above.

In order to achieve the above object, the present invention

25 provides, according to an aspect thereof, an information recording medium, which comprises a substrate, a recording layer, and a resin layer, wherein the substrate is formed with a pit corresponding to a read only area and a groove corresponding to a

recording/reproducing area without overlapping with each other,  
and wherein a reflectivity of the recording layer is more than 10 %,  
the information recording medium is characterized in that a  
push-pull signal output T1 reproduced from the read only area and  
5 another push-pull signal output T2 reproduced from the  
recording/reproducing area is more than 0.1 respectively and  
further  $1.5 \geq T1/T2 \geq 0.5$ .

Other object and further features of the present invention  
will be apparent from the following detailed description when read  
10 in conjunction with the accompanying drawings.

#### BRIEF DESCRIPTION OF DRAWINGS

## DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

With referring to drawings, details common to all  
25 embodiments of the present invention are explained first.

Fig. 1 is a plan view of an information recording medium in a disk shape according to an embodiment of the present invention.

Fig. 2 is a cross sectional view of the information recording

medium shown in Fig. 1.

Fig. 3 is another cross sectional view of the information recording medium shown in Fig. 1.

In Fig. 1, an information recording medium 1 in a disk shape  
5 comprises a read only area 31 and a recording/reproducing area 32.  
As shown in Fig. 1, the read only area 31 and the  
recording/reproducing area 32 is allocated in an innermost  
circumference area and an outer circumference area of the  
information recording medium 1 respectively. However, these  
10 allocations can be reversely arranged. Further, these two areas  
are formed not so as to overlap with each other. Some gap existing  
between two areas can be allowable. Furthermore, a plurality of  
the read only and recording/reproducing areas 31 and 32 can also  
be allowable.

15 Fig. 2 shows a fundamental configuration of an information  
recording medium 1 of the present invention. The information  
recording medium 1 of the present invention is resemble to that of  
the prior art in appearance, so that the same drawing is used for  
explaining the present invention. Fig. 3 also shows a fundamental  
20 configuration of an information recording medium 2 of the present  
invention. The configuration shown in Fig. 3 is a same as that  
shown in Fig. 2 except a reading out direction, that is, an optical  
path. An optical path will be explained.

As shown in Figs. 2 and 3, the information recording medium  
25 1 or 2 comprises a substrate 10, a recording layer 13 and a resin  
layer 14. A microscopic pattern is formed on a surface of the  
substrate 10 at a boundary between the substrate 10 and the  
recording layer 13. Microscopic patterns 11 and 12 are formed in

areas corresponding to the read only area 31 and the recording/reproducing area 32 respectively without overlapping with each other.

Further, these microscopic patterns 11 and 12 have a depth of "d1" and "d2" respectively. Either cases can be acceptable whether or not the depth "d1" of the microscopic patterns 11 is a same as the depth "d2" of the microscopic patterns 12. However, a depth must be designated so as to be able to obtain a range of push-pull signal output, which will be depicted.

Layers composed of the substrate 10, the recording layer 13, and the resin layer 14 are formed in parallel to each other. The resin layer 14 is adhered on the recording layer 13 with continuously covering over all areas including at least the read only area 31 and the recording/reproducing area 32. Although recording or reproducing by light beam is performed on the recording layer 13, it is arbitrarily determined that a laser beam having a wavelength of  $\lambda$  nm, which is stopped down by a objective lens having a numerical aperture of NA, is irradiated from either side of the information recording medium 1. In other words, it is arbitrarily determined whether the laser beam is irradiated from the substrate 10 side or the resin layer 14 side. Further, a path of irradiating the laser beam, that is, an optical path has a certain refractive index "n" for the wavelength  $\lambda$ . An effective optical length is determined by the refractive index "n". The substrate 10 is illustrated as an optical path in Fig. 2. However, the resin layer 14 can be used as an optical path as shown in Fig. 3. The refractive index "n" of these optical paths is desirable to be 1.4 through 1.7 in consideration of

interchangeability with current optical disks, more desirable to be 1.45 through 1.65. Further, if birefringence of the optical path is designated to be less than 100 nm by double paths, deviation of reproduction output can be sufficiently suppressed, so that it is  
5 most desirable.

Synthetic resins of high strength and various ceramics can be utilized for a material of the substrate 10. Actual materials are such resins as polycarbonate, polymethyle methacrylate, polystyrene, polycarbonate-polystyrene copolymer, polyvinyl  
10 chloride, alicyclic polyorefin, polymethyle pentene, polyacetate resin, and various copolymer having a resin frame of them, and such synthetic resin as block polymer, and such ceramics as soda aluminosilicate glass, boron silicate glass, and silica glass.

Further, the recording layer 13 is at least made of a  
15 recording material of which a reflectivity is more than 10 % at the wavelength  $\lambda$ . Actually, following materials can be used for a recording material of enabling recordable or write once recording: such dye materials as cyanine dye, phthalocyanine dye, naphthalocyanine dye, azo dye, and naphthoquinone dye.  
20 Furthermore, a phase change recording material, so called, and a magneto-optical recording material can be used for a recording material of enabling overwrite. Typical phase change recording materials are as follows: alloys made of some materials selected from indium, antimony, tellurium, selenium, germanium, gallium,  
25 bismuth, platinum, gold, silver, copper, tin, sulfur, and aluminum, wherein an alloy includes compound such as oxide, nitride, and carbide. Moreover, in a case of magneto-optical recording material, there existed an alloy, which contains at least a transition metal

and a rare earth element. The alloy is made of some materials selected from terbium, cobalt, iron, gadolinium, neodymium, dysprosium, bismuth, palladium, samarium, holmium, praseodymium, manganese, titanium, erbium, ytterbium, lutetium, chromium, tin, platinum, wherein an alloy includes compound such as oxide, nitride, and carbide. In addition thereto, the recording layer 13 can be multi-layered or laminated by an optical interference film such as SiN, SiC, SiO, ZnS, ZnSSiO, AlO, GeN, MgF, InO, and ZrO, and an optical reflection film such as aluminum, gold, silver, and titanium for a purpose of improving performance. In order to perform high density recording and reproducing, the recording layer 13 can be laminated by a super resolution masking film or a contrast enhancing film, which is commonly known.

The resin layer 14 is provided for protecting the recording layer 13 chemically and physically, and can be selected from thermosetting resins, ultra violet ray curable resins, various radiation including visible light curable resins, electron beam curable resins, moisture curable resins, and multiple liquid mixture curable resins. A surface of the resin layer 14 can be printed if necessary.

Fig. 5 is a plan view of a boundary area between a read only area and a recording/reproducing area of an information recording medium partially enlarged according to the present invention. There existed a gap having a distance of "G" (hereinafter referred to a gap "G") between the read only area 31 and the recording/reproducing area 32 caused by a manufacturing process of the information recording medium 1. In other words, as shown

in Fig. 5, the gap "G" exists between the microscopic patterns 11 of the read only area 31 and the microscopic patterns 12 of the recording/reproducing area 32. Basically, a recording/reproducing apparatus can jump across the gap "G" by forcing to drive a pickup or a like. According to our experiment, the jumping motion can be smoothly performed by setting the gap "G" in less than 25  $\mu$ m.

As shown in Fig. 5, the microscopic patterns 11 of the read only area 31 is a group of pit 21, which is engraved by what is called a recording method of cutting. A track is composed of continuing groups of the pit 21. The microscopic patterns 12 utilized for the recording/reproducing area 32 are not formed in the read only area 31. A gap between each track is in a distance of P1 (hereinafter referred to a track pitch P1). The pit 21 is modulated by a well-known modulation method and formed a pit in various length. A minimal pit length closely relating to quality of a reproduction signal is defined as L1. The groups of pit 21 can be meandered or wobbled by applying a sinusoidal deflection to the pit 21 when the pit 21 is recorded with cutting. It is acceptable that wobbling is recorded by either the CLV (constant linear velocity) or the CAV (constant angular velocity) method. Further, a specific code, which can not be rewritten by a user, is recorded in the read only area 31. The specific code is such a key or code as a key for ciphering, a key for deciphering, a code for permitting to record, a code for refusing to record, and a disk serial number inherent to each disk. In addition thereto, a lead-in signal can be recorded as a same manner as that of a current read only disk.

The microscopic patterns 12 in the recording/reproducing area 32 are composed of a group of groove 22. A gap between each

groove 22 is called a land 23 commonly. Each groove 22 is spaced in a distance of P2 (hereinafter referred to a track pitch P2). The groove 22 can also be wobbled by applying a sinusoidal deflection to the groove 22 when the groove 22 is recorded with cutting. It is  
5 acceptable that wobbling is recorded by either the CLV or the CAV method. Further, an address pit, which specifies an address number, can be allocated in between each groove 22, that is, in the land 23.

Recording an information by a user is explained next.

10 Fig. 6 is a plan view of the interface area as same as that of shown in Fig. 5 with showing a mark 24 written in the groove 22.

Fig. 7 is a plan view of the interface area as same as that of shown in Fig. 5 with showing the mark 24 written in the land 23.

Recording is performed as shown in Fig.6. That is to say, the  
15 mark 24 is formed in the groove 22 by focusing a laser beam for recording on the groove 22. The mark 24 is modulated by a well-known modulating method, and then formed in various lengths. A minimal pit length closely relating to quality of a reproduction signal is defined as L2. As shown in Fig. 7, the mark 24 can be  
20 written in between each groove 22, that is, in the land 23. Further, the mark 24 can be written in both the groove 22 and the land 23 although not shown in any drawings.

The well-known modulation method applied for the read only and recording/reproducing areas 31 and 32 is a signal of which  
25 minimal mark length is specified to one of lengths such as 2T, 3T, 4T, and 5T. In a case of a signal system in which a minimal pit length or a minimal mark length is specified to 2T, for example, such a signal system as an eight to twelve (8/12) modulation,

which is composed of signals from 2T to 8T, can be utilized. Further, in a case of a signal system in which a minimal pit length or a minimal mark length is specified to 3T, signal systems such as an eight to fourteen (8/14) modulation, an eight to fifteen (8/15) modulation, and an eight to seventeen (8/17) modulation, which are composed of signals from 3T to 11T, and another signal system such as an eight to sixteen (8/16) modulation, which is composed of signal from 3T to 11T and 14T, can be utilized. In these read only and recording/reproducing areas 31 and 32, each signal in the respective areas can be modulated by different modification methods. However, a same modification method is desirable to be employed, in consideration of convenience of a recording/reproducing apparatus. It is also desirable by the same reason that  $P1 = P2$  and  $L1 = L2$ .

In order to enable a traverse reproduction over the read only area 31 and the recording/reproducing area 32, the depth  $d1$  and  $d2$  of respective areas of the information recording medium 1 according to the present invention are adjusted so as to enable to obtain a predetermined push-pull signal. A predetermined push-pull signal satisfies following inequalities simultaneously with defining that a push-pull signal output of the read only area 31 is  $T1$  and a push-pull signal output of the recording/reproducing area 32 before recording is  $T2$ .

$$T1 \geq 0.1$$

$$T2 \geq 0.1 \text{ and}$$

$$1.5 \geq T1/T2 \geq 0.5.$$

Further, in order to stabilize a traverse reproduction over areas, respective push-pull signal outputs are desirable to be within a

range of satisfying following inequalities simultaneously:

$$T1 \geq 0.15$$

$$T2 \geq 0.15 \text{ and}$$

$$1.4 \geq T1/T2 \geq 0.6.$$

- 5 A range of tracking signal of the information recording medium according to the present invention is obtained by a limiting value, which is obtained by reproducing the information recording medium actually loaded in a player by means of the push-pull method. A result of experiment is shown in Table 1. By  
10 examining tracking ability in the read only area 31 with respect to T1, tracking is completely disabled by T1 in less than 0.08.

[Table 1]

T1	Tracking
0.08	Disable
0.10	Enable
0.15	Enable
0.18	Enable
0.25	Enable

- Further, Table 2 shows a result of examining tracking ability in the recording/reproducing area 31 with respect to T2. Tracking  
15 is completely disabled by T2 in less than 0.08 as same situation as that of T1.

[Table 1]

T2	Tracking
0.08	Disable
0.10	Enable
0.15	Enable
0.22	Enable
0.31	Enable
0.45	Enable

- It is found by the above experiment that a value of both T1 and T2 must be more than 0.1. Furthermore, the value is desirable  
20 to be more than 0.15, in consideration of a case that the

information recording medium 1 is dusted or scratched.

A limitation of continuous reproducibility over two areas is caused by that there is existed a limit in a dynamic range of a servo circuit of a recording apparatus. In other words, it is  
5 required that a difference between T1 and T2 is smaller. Therefore, with respect to the information recording medium 1, which satisfies the inequalities of  $T1 \geq 0.1$  and  $T2 \geq 0.1$ , a limiting value is obtained by performing a traverse reproduction over two areas for various disk samples of T1/T2. A result is shown in Table  
10 3 below. As shown in Table 3, the traverse reproduction over two areas is enabled in a case that T1/T2 is within a range from 0.5 to 1.5. However, the value is desirable to be within a range from 0.6 to 1.4, in consideration of a case that the information recording medium 1 is dusted or scratched.

15 [Table 3]

T1	T2	T1/T2	Traverse reproduction over areas
0.10	0.10	1.0	Enable
0.10	0.20	0.5	Enable
0.10	0.25	0.4	Disable
0.15	0.22	0.7	Enable
0.20	0.12	1.7	Disable
0.20	0.13	1.5	Enable
0.20	0.28	0.7	Enable
0.20	0.40	0.5	Enable
0.20	0.45	0.4	Disable
0.22	0.16	1.4	Enable
0.25	0.16	1.6	Disable
0.25	0.17	1.5	Enable
0.25	0.25	1.0	Enable
0.25	0.34	0.7	Enable
0.25	0.44	0.6	Enable

A push-pull signal output is defined as follows: a push-pull signal is a signal, which is produced by calculating respective outputs from a 4-division photodetector utilized for a

recording/reproducing apparatus as a pickup.

Fig. 9 is a cross sectional view of a 4-division photodetector 9 utilized for recording and reproducing the information recording medium 1 according to the present invention.

5        In Fig. 9, a horizontal and vertical axes are a radial direction and a tangential direction (track direction) respectively in corresponding to Figs. 5 through 7. Reproduced outputs of the 4-division photodetector 9 are Ia, Ib, Ic, and Id respectively. An output difference between an inner circumference side and an  
10    outer circumference side, that is,  $|(Ia + Ib) - (Ic + Id)|$  is measured by an AC (alternative current) coupling, and then total outputs, that is,  $|(Ia + Ib + Ic + Id)|$  is measured by a DC (direct current) coupling. A push-pull signal "T" is a ratio of these two values and defined as follows:

15        
$$T = |(Ia + Ib) - (Ic + Id)| / |(Ia + Ib + Ic + Id)|.$$

As mentioned above, in the information recording medium 1 having at least the read only and recording/reproducing areas 31 and 32, in order to enable the traverse reproduction over two areas, the present invention specifies a push-pull signal output to a  
20    predetermined range.

#### [First embodiment]

Fig. 1 is a plan view of an information recording medium in a disk shape according to an embodiment of the present invention.

25        Fig. 4 is a cross sectional view of the information recording medium shown in Fig. 1 according to a first embodiment of the present invention.

In Fig. 1, an information recording medium 3 comprises a

read only area 31 formed a ring shape in an inner circumference area and a recording/reproducing area 32 formed a ring shape in an area outside the read only area 31. As shown in Fig. 4, the information recording medium 3 comprises a substrate 10, a recording layer 13, a resin layer 14 and a dummy substrate 15. The resin layer 14 is adhered on the recording layer 13 with continuously covering over two areas including the read only area 31 and the recording/reproducing area 32. The substrate 13 comprises polycarbonate of which a refractive index "n" is 1.58 at a wavelength  $\lambda$  of 650 nm. The recording layer 13 comprises a phase change material having a reflectivity of more than 15 % such as an alloy of antimony, tellurium, and a metal having a melting point of less than 1100 °C. Actually, the alloy is composed of silver, indium, antimony, and tellurium (AgInSbTe), for example. The alloy is sandwiched by dielectric such as ZnSSiO and further laminated by a reflection film of an aluminum alloy, and then they are formed as a recording layer having a reflectivity of 18 to 30 %. The resin layer 14 comprises an ultra violet curable resin and is adhered to the dummy substrate 15 with laminated.

Fig. 8 is a plan view of microscopic patterns 11 and 12 formed on the substrate 10 typically before recording information.

In Fig. 8, a gap "G" between the microscopic pattern 11 and 12, that is, a gap "G" between the read only area 31 and the recording/reproducing area 32 is 25  $\mu\text{m}$ . The microscopic patterns 11 corresponding to the read only area 31 is recorded spirally by the CLV method, that is, a group of pit 21, which is wobbled sinusoidally. A width of wobbling is 0.009 to 0.017  $\mu\text{m}$ . An average track pitch P1 of the microscopic patterns 11 is 0.74  $\mu\text{m}$ .

With respect to a modification method of the read only area 31, the 8/16-modification method is utilized. A minimal pit length of the pit 21 is  $0.4 \mu\text{m}$ .

On the other hand, the recording/reproducing area 32 is  
5 composed of a sinusoidally wobbled groove 22 and an address pit  
25 formed on a land 23, which is provided between each groove 22  
with being adjacent to a groove wall. These groove 22 and address  
pit 25 is also formed in a spiral. A width of wobbling is  $0.009$  to  
 $0.017 \mu\text{m}$ . An average track pitch P2 of the microscopic patterns  
10 12 is  $0.74 \mu\text{m}$ . In addition thereto, the address pit 25 is a pit  
recorded with an address, which is useful when recording, and is  
recorded throughout the information recording medium from an  
innermost circumference area to an outermost circumference area  
in accordance with a certain rule. Recording is performed by  
15 forming a mark (not shown) in the groove 22. With respect to a  
recording modulation method of the recording /reproducing area  
32, the 8/16-modulation method is utilized as same as that of the  
read only area 31. A minimal pit length L2 (not shown) of a  
recorded mark in the groove 2 is  $0.4 \mu\text{m}$  as a same length as the  
20 minimal pit length L1.

When such the information recording medium is reproduced  
by using a pickup having a wavelength  $\lambda$  of  $650 \text{ nm}$  and a  
numerical aperture NA of  $0.6$ , in order to accomplish a range of  
push-pull signal output, that is,  $T1 \geq 0.1$ ,  $T2 \geq 0.1$ , and  $1.5 \geq$   
25  $T1/T2 \geq 0.5$ , it is effective to optimize depths  $d1$  and  $d2$  of the  
microscopic patterns 11 and 12 in the read only area 31 and the  
recording/reproducing area 32 respectively.

Fig. 10 is a graph showing a relation between the depth  $d1$  of

the read only area 31 of the information recording medium and a push-pull signal output T1 according to the present invention. A vertical and horizontal axes represent a value of  $(d1 \times n)$  divided by  $\lambda$ , that is,  $(nd1/\lambda)$  and a push-pull signal output T1 respectively. The T1 is defined by the sine function of the P1. According to Fig. 10, the  $(nd1/\lambda)$  is specified to 0.03 through 0.22 so as to realize  $T1 \geq 0.1$ . Further, a reproduction jitter, which is fluctuation in a time axis direction, decreases as far as the  $(nd1/\lambda)$  approaches to 0.25, so that it is proper for the  $(nd1/\lambda)$  to be 0.12 through 0.22 in a depth.

Fig. 11 is a graph showing a relation between the depth d2 of the recording/reproducing area 32 of the information recording medium and a push-pull signal output T2 according to the present invention. The T2 is defined by the sine function of the P2 as same as the T1. However, in a case of a groove, a value of the T2 is approximately twice a value of the T1. According to Fig. 11, the  $(nd2/\lambda)$  is specified to 0.02 through 0.23 so as to realize  $T2 \geq 0.1$ . Further, when the information recording medium is recorded and reproduced, a jitter decreases in conjunction with reflectivity, which increase, as far as the  $(nd2/\lambda)$  approaches to zero, so that it is proper for the  $(nd2/\lambda)$  to be 0.02 through 0.12 in a depth.

Furthermore, a reproduction jitter can be obtained in accordance with the Annex "F" of JIS-X-6241 (Japanese Industrial Standard). According to the Standard, a jitter is required to be not more than 8 %. In other words, if a jitter exceeds 8 %, reading out a reproduction signal is seriously affected by disturbance such as disk tilt. By recording and reproducing practically, and by optimizing the depths d1 and d2, ranges of  $(nd1/\lambda)$  and  $(nd2/\lambda)$

are as follows:

( $nd1/\lambda$ ) is within a range from 0.17 to 0.22, wherein the T1 is 0.1 through 0.22, and

( $nd2/\lambda$ ) is within a range from 0.02 to 0.10 wherein the T2 is 0.1 through 0.42.

With referring to Figs. 10 and 11, ( $nd1/\lambda$ ) and ( $nd2/\lambda$ ) can be selected out from the ranges shown above so as for the T1/T2 to be 0.5 through 1.5. It is specified that ( $nd1/\lambda$ ) = 0.17 and ( $nd2/\lambda$ ) = 0.06 in this embodiment. In this case, T1 = 0.22 and T2 = 0.31, and then it is obtained that T1/T2 = 0.7. Accordingly, the push-pull conditions of the present invention such that  $T1 \geq 0.1$ ,  $T2 \geq 0.1$ , and  $1.5 \geq T1/T2 \geq 0.5$  can be sufficiently satisfied. Further, reproduction jitter in the read only area 31 and the recording/reproducing area 32 are 7.9 % and 6.2 % respectively. Both jitter values sufficiently satisfy the standard. Furthermore, by continuously reproducing two areas, it is confirmed that a continuous reproduction can jump across the two areas without any problems.

## [Second Embodiment]

Parameters of this embodiment are a same as those of the first embodiment except for ( $nd1/\lambda$ ) = 0.18 and ( $nd2/\lambda$ ) = 0.08. Further, the gap "G" between the read only area 31 and the recording/reproducing area 32 are specified to 20  $\mu$ m. By these parameters, it is obtained that T1 = 0.19 and T2 = 0.37, and then T1/T2 = 0.5 is obtained. Accordingly, the push-pull conditions of the present invention such that  $T1 \geq 0.1$ ,  $T2 \geq 0.1$ , and  $1.5 \geq T1/T2 \geq 0.5$  can be satisfied. Further, reproduction jitter in the

read only area 31 and the recording/reproducing area 32 are 7.1 %  
and 6.5 % respectively. Both jitter values sufficiently satisfy the  
standard. Furthermore, by continuously reproducing two areas, it  
is confirmed that a continuous reproduction can jump across the  
5 two areas without any problems.

#### [Third Embodiment]

Parameters of this embodiment are a same as those of the  
first embodiment except for  $(nd1/\lambda) = 0.175$  and  $(nd2/\lambda) = 0.067$ .  
10 Further, the gap "G" between the read only area 31 and the  
recording/reproducing area 32 are assigned to  $0.74 \mu\text{m}$ , which is  
the same value as P1 and P2. By these parameters, it is obtained  
that  $T1 = 0.20$  and  $T2 = 0.33$ , and then  $T1/T2 = 0.6$  is obtained.  
Accordingly, the push-pull conditions of the present invention  
15 such that  $T1 \geq 0.1$ ,  $T2 \geq 0.1$ , and  $1.5 \geq T1/T2 \geq 0.5$  can be  
satisfied. Further, reproduction jitter in the read only area 31 and  
the recording/reproducing area 32 are 7.5 % and 6.3 % respectively.  
Both jitter values sufficiently satisfy the standard. Furthermore,  
by continuously reproducing two areas, it is confirmed that a  
20 continuous reproduction can be performed without stopping at a  
boundary between two areas.

#### [Fourth Embodiment]

Parameters of this embodiment are a same as those of the  
25 first embodiment except for  $(nd1/\lambda) = 0.2$  and  $(nd2/\lambda) = 0.04$ .  
Further, the gap "G" between the read only area 31 and the  
recording/reproducing area 32 are assigned to  $0.74 \mu\text{m}$ , which is  
the same value as P1 and P2. By these parameters, it is obtained

that  $T1 = 0.15$  and  $T2 = 0.22$ , and then  $T1/T2 = 0.66$  is obtained. Accordingly, the push-pull conditions of the present invention such that  $T1 \geq 0.1$ ,  $T2 \geq 0.1$ , and  $1.5 \geq T1/T2 \geq 0.5$  can be satisfied. Further, reproduction jitter in the read only area 31 and  
5 the recording/reproducing area 32 are 6.8 % and 5.8 % respectively. Both jitter values sufficiently satisfy the standard. Furthermore, by continuously reproducing two areas, it is confirmed that a continuous reproduction can be performed without stopping at a boundary between two areas.

10

[Fifth Embodiment]

Parameters of this embodiment are a same as those of the first embodiment except for  $(nd1/\lambda) = 0.17$  and  $(nd2/\lambda) = 0.04$ . Further, the gap "G" between the read only area 31 and the  
15 recording/reproducing area 32 are assigned to  $0.74 \mu m$ , which is the same value as P1 and P2. By these parameters, it is obtained that  $T1 = 0.22$  and  $T2 = 0.22$ , and then  $T1/T2 = 1.0$  is obtained. Accordingly, the push-pull conditions of the present invention such that  $T1 \geq 0.1$ ,  $T2 \geq 0.1$ , and  $1.5 \geq T1/T2 \geq 0.5$  can be  
20 satisfied. Further, reproduction jitter in the read only area 31 and the recording/reproducing area 32 are 7.9 % and 5.9 % respectively. Both jitter values sufficiently satisfy the standard. Furthermore, by continuously reproducing two areas, it is confirmed that a continuous reproduction can be performed without stopping at a  
25 boundary between two areas.

[Sixth Embodiment]

Parameters of this embodiment are a same as those of the

first embodiment except for  $(nd1/\lambda) = 0.17$  and  $(nd2/\lambda) = 0.03$ . Further, the gap "G" between the read only area 31 and the recording/reproducing area 32 are assigned to  $0.74 \mu m$ , which is the same value as P1 and P2. By these parameters, it is obtained  
5 that  $T1 = 0.22$  and  $T2 = 0.167$ , and then  $T1/T2 = 1.4$  is obtained. Accordingly, the push-pull conditions of the present invention such that  $T1 \geq 0.1$ ,  $T2 \geq 0.1$ , and  $1.5 \geq T1/T2 \geq 0.5$  can be satisfied. Further, reproduction jitter in the read only area 31 and the recording/reproducing area 32 are 7.9 % and 5.5 % respectively.  
10 Both jitter values sufficiently satisfy the standard. Furthermore, by continuously reproducing two areas, it is confirmed that a continuous reproduction can be performed without stopping at a boundary between two areas.

15 [Seventh Embodiment]

Parameters of this embodiment are a same as those of the first embodiment except for  $(nd1/\lambda) = 0.17$  and  $(nd2/\lambda) = 0.028$ . Further, the gap "G" between the read only area 31 and the recording/reproducing area 32 are assigned to  $0.74 \mu m$ , which is  
20 the same value as P1 and P2. By these parameters, it is obtained that  $T1 = 0.25$  and  $T2 = 0.158$ , and then  $T1/T2 = 1.5$  is obtained. Accordingly, the push-pull conditions of the present invention such that  $T1 \geq 0.1$ ,  $T2 \geq 0.1$ , and  $1.5 \geq T1/T2 \geq 0.5$  can be satisfied. Further, reproduction jitter in the read only area 31 and  
25 the recording/reproducing area 32 are 7.9 % and 5.4 % respectively. Both jitter values sufficiently satisfy the standard. Furthermore, by continuously reproducing two areas, it is confirmed that a continuous reproduction can be performed without stopping at a

boundary between two areas.

[Eighth Embodiment]

An embodiment of the information recording medium, which  
5 is recorded or reproduced by using a blue semiconductor laser  
beam having a wavelength  $\lambda$  of 405 nm is explained next as an  
expanded embodiment of the present invention. An information  
recording medium 2 has a cross sectional configuration shown in  
Fig. 3. The information recording medium 2 comprises a substrate  
10 10 composed of polycarbonate, a recording layer 13 composed of a  
phase change material having reflectivity of more than 10 %,  
particularly, an alloy composed of antimony, tellurium, and a  
metal having a melting point of less than 1100 °C, and a resin  
layer 14. Further, the recording layer 13 actually comprises an  
15 alloy composed of silver, indium, antimony, and tellurium  
(AgInSbTe), for example. The alloy is sandwiched by dielectric  
such as ZnSSiO and further laminated by a reflection film of an  
aluminum alloy, and then they are formed as a recording layer  
having a reflectivity of 10 to 25 %. The resin layer 14 comprises  
20 polycarbonate having a refractive index "n" of 1.6 at the  
wavelength  $\lambda$  of 405 nm.

Microscopic patterns on a surface of the substrate 10 in both  
the read only area 31 and the recording/reproducing area 32 are  
recorded spirally by the CAV method with being wobbled  
25 sinusoidally. Other parameters are the same as those of the first  
embodiment except for an average track pitch such that P1 and P2  
is 0.374  $\mu\text{m}$ , wherein respective width of wobbling is 0.006 to  
0.011  $\mu\text{m}$ . With respect to a modification method, the D8/15-

modification method, which is one variation of the 8/15-modulation method and disclosed in the Japanese Patent Application No 11-23316/1999, is utilized. A minimal pit length L1 and a minimal mark length L2 is 0.2  $\mu\text{m}$  respectively.

5        Parameters in the read only and recording/reproducing areas 31 and 32 are specified to  $(nd1/\lambda) = 0.18$  and  $(nd2/\lambda) = 0.08$  respectively. Further, the gap "G" between the read only area 31 and the recording/reproducing area 32 are specified to 0.374  $\mu\text{m}$ , which is the same value as P1 and P2. By these parameters, it is  
10    obtained that  $T1 = 0.19$  and  $T2 = 0.38$ , and then  $T1/T2 = 0.5$  is obtained. Accordingly, the push-pull conditions of the present invention such that  $T1 \geq 0.1$ ,  $T2 \geq 0.1$ , and  $1.5 \geq T1/T2 \geq 0.5$  can be satisfied. Further, by continuously reproducing two areas, it is confirmed that a continuous reproduction can jump  
15    across the two areas without any problems.

[Ninth Embodiment]

Parameters of this embodiment are a same as those of the seventh embodiment except for  $(nd1/\lambda) = 0.17$  and  $(nd2/\lambda) =$   
20    0.028. Further, the gap "G" between the read only area 31 and the recording/reproducing area 32 are assigned to 0.374  $\mu\text{m}$ , which is the same value as P1 and P2. By these parameters, it is obtained that  $T1 = 0.26$  and  $T2 = 0.17$ , and then  $T1/T2 = 1.5$  is obtained. Accordingly, the push-pull conditions of the present invention  
25    such that  $T1 \geq 0.1$ ,  $T2 \geq 0.1$ , and  $1.5 \geq T1/T2 \geq 0.5$  can be satisfied. Further, by continuously reproducing two areas, it is confirmed that a continuous reproduction can be performed without stopping at a boundary between two areas.

While the invention has been described above with reference to specific embodiments thereof, it is apparent that many changes, modifications and variations in the arrangement of equipment and devices and in materials can be made without departing from the invention concept disclosed herein.

Fig. 12 is a plan view of an information recording medium in a card shape according to the present invention.

Fig. 13 is a plan view of another information recording medium in a card shape according to the present invention.

Each composing element in some embodiments shown by drawings can be interchanged or replaced by other composing element described in the specification. For example, in the first and second embodiments, the information recording medium is exemplified by a disk shaped one. However, as shown in Fig. 12, an information recording medium 101 in a card shape provided with a read only area 131 in a stripe and a recording/reproducing area 132 in a stripe can be utilized. Further, as shown in Fig. 13, an information recording medium 201 in a card shape provided with a read only area 231 in a ring shape and a recording/reproducing area 232 in a ring shape can also be utilized.

Furthermore, in the first and second embodiments, a phase change recording material is utilized for the recording layer 13. However, the material is not limited to a phase change recording material. A magneto-optical recording material and a recordable type recording material such as a dye material can also be utilized.

More, a wavelength of a laser beam utilized for reproducing or recording/reproducing is specified as 650 and 405 nm. However,

a wavelength is not limited to them. Any length such as 830, 635, 515, 460, 430, and 370 nm, and their adjacent wavelength can be utilized. Moreover, with respect to a numerical aperture NA of a lens, any NA such as 0.4, 0.45, 0.55, 0.65, 0.7, 0.75, 0.8, 0.85, and  
5 0.9 other than 0.60 can be applicable. In addition thereto, a lens having an NA of more than 1.0, which is represented by a solid immersion lens, can also be applicable.

According to an aspect of the present invention, as depicted above, the information recording medium, which comprises at  
10 least the read only area 31 and the recording/reproducing area 32, can perform a traverse reproduction over two areas by specifying push-pull signal outputs from the read only area 31 and the recording/reproducing area 32 to a predetermined range.
